CSC 211: Computer Programming Structs

Michael Conti

Department of Computer Science and Statistics University of Rhode Island

Fall 2023

Original design and development by Dr. Marco Alvarez

Structures

- Definition is generally outside any function
 new 'data type' will be available to all code that follows
- Structures can be declared in the same way as basic data types
- Can also use { } notation for initialization
- Use the **dot operator** for accessing data members

2

Structures

```
struct structureName {
    member1;
    member2;
    member3;
    .
    .
    memberN;
};
```

Structures in C++ are user defined data types which are used to store multiple items (members) of possibly different data types

Example

```
// defining the struct
struct Point {
   int x;
   int y;
};

int main() {
   // creating a variable
   struct Point p1;
}
```

Initializing ... // defining the struct struct Point { int x; int y; }; int main() { // initializing (follows order) struct Point p1 = { 10, 20 }; }

```
#include <iostream>

struct Point {
    int x;
    int y;
};

int main() {
    struct Point p1 = { 10, 20 };
    p1.x += 5;
    std:.cout << p1.x << ' ' << p1.y << '\n';
}</pre>
```

The dot operator

```
#include <iostream>

struct Point {
    int x;
    int y;
};

int main() {
    struct Point p1 = { 10, 20 };
    struct Point p2 = { 30, 40 };
    struct Point p3 = { 50, 60 };
    p1.x += 5; p2.y += 10; p3.y += 15;
}
```

```
DISPLAY 10.2 Member Values
     struct CDAccount
          double balance;
          double interestRate;
          int term; //months until maturity
 6
7
      int main()
 8
                                          balance
 9
         CDAccount account;
                                          interestRate
                                                                         account
10
11
                                          term
12
                                          balance
                                                             1000.00
13
         account.balance = 1000.00;
14
                                          interestRate
                                                                         account
15
                                         balance
                                                             1000.00
16
         account.interestRate = 4.7;
17
                                         interestRate
                                                                         account
18
                                         term
                                         balance
                                                             1000.00
19
         account.term = 11:
20
                                          interestRate
                                                                 4.7
                                                                         account
21
                     from: Problem Solving with C++, 10th Edition, Walter Savitch
```

Array of structures

```
#include <iostream>
struct Point2D {
    double x;
    double y;
};
int main() {
    Point2D mypoint;
    Point2D myarray[5];
    mypoint.x = 10;
    mypoint.y = 20;
    for (int i = 0 ; i < 5 ; i ++) {
        myarray[i].x = 0;
        myarray[i].y = i;
    }
}</pre>
```

Arrays and Structures

- When using arrays as structs member, the index goes at the end
 - ✓ student.grades[i]
- When using structs as arrays elements, the index goes after the struct name
 - √ students[i].finalGrade

10

Functions

```
// defining the struct
struct Point {
    int x;
    int y;
};

void distance(Point P1, Point P2);
```

Passing structures to functions

A struct can be passed as a parameter either by value or by reference

```
void printPoint(Point &somePoint){
   std::cout << somePoint.x;
   std::cout << somePoint.y;
};</pre>
```

• A function can return a value of type struct

```
Point incrementPoint(Point somePoint){
    somePoint.x+=1;
    somePoint.y+=1;
    return somePoint;
};
```

Passing structures to functions

```
DISPLAY 10.1 A Structure Definition
      //Program to demonstrate the CDAccount structure type.
                                                                                                void getData(CDAccount& theAccount)
     #include <iostream>
                                                                                                    cout << "Enter account balance: $";
      //Structure for a bank certificate of deposit:
       struct CDAccount
                                                                                                    cin >> theAccount.balance;
                                                                                                    cout << "Enter account interest rate: ";
cin >> theAccount.interestRate;
                                                                                                    cout << "Enter the number of months until maturity\n"
        double interestRate:
                                                                                                          << "(must be 12 or fewer months): ";
          int term; //months until maturity
                                                                                                    cin >> theAccount.term;
       void getData(CDAccount& theAccount);
      //Postcondition: theAccount.balance and theAccount.interestRate
       //have been given values that the user entered at the keyboard
18
      int main()
          CDAccount account
          getData(account);
         rateFraction = account.interestRate / 100.0;
interest = account.balance * rateFraction * (account.term / 12.0);
         account.balance = account.balance + interest;
         cout.setf(ios::fixed):
         cout.setf(ios::showpoint);
         cout.precision(2);
cout << "When your CD matures in "</pre>
               << account.term << " months,\n"
<< "it will have a balance of $"</pre>
                << account.balance << endl;
                                             from: Problem Solving with C++, 10th Edition, Walter Savitch
```

Be careful of same member names

```
// defining the struct
struct Point {
    int x;
    int y;
};

struct Character {
    int x;
    int y;
    std::string name;
};

Compiler can keep track but it's harder for humans
```

14

Structs and Pointers

```
struct Books {
    std::string title;
    std::string author;
    std::string subject;
    int book_id;
};
```

Pointers and Structs

You can define pointers to structures in very similar way as you define pointer to any other variable

```
struct Books *struct_pointer;
```

Now, you can store the address of a structure variable in the above defined pointer variable.

```
struct_pointer = &Book1;
```

Structs and Pointers

```
void printBook( struct Books *book ) {
  std::cout << "Book title : " << book->title;
  std::cout << "Book author: " << book->author;
  std::cout << "Book subject : " << book->subject;
  std::cout << "Book id : " << book->book id;
struct Books {
   std::string title;
   std::string author;
   std::string subject;
    int book_id;
};
                             int main(){
                                struct Books Book1;
                                Book1.title = "Learn C++ Programming"
                                Book1.author = "Chand Miyan"
                                Book1.subject = "Computer Science"
                                 printBook( &Book1 );
```

Example

- · Write a Student struct that contains
 - √ Name
 - √ StudentID
 - √ Major
- Implement functions:
 - ✓ void buildStudent(Student &someStudent)
 - Initialize member variables of student Struct
 - void changeMajor(Student &someStudent);
 - Change the major of a student structure
 - void printStudent(Student &someStudent);
 - Prints out all member variables of student structure
